I have a problem with the measurement of electrical circuits. Is there a way to measure an electrical circuit's transfer function that is correct and easy to use? What I mean by transfer function is the relation between the current and the

voltage in the circuit. I used to use a measurement technique that worked well but is a bit old: a voltage divider. I had for instance two resistors that can be connected in parallel or in series and I used one as a reference for the other. The voltage on the reference resistor was measured and then the voltage of the other resistor was divided by the reference to get the ratio of the resistors. However, the problem is that the current can flow through the

resistor that I'm using as a reference and I don't know if that is good or bad. But I can control the current through the resistors and this could influence the reference resistor in a way that I don't know if it is good or bad. I have thought about using a multimeter but I don't think that I can control the current through the circuit and I think that the current is an important factor. Do you know a correct and easy to use technique to measure the transfer function of

a circuit? A: [There are] a couple of assumptions here: 1. The resistors are ideal, which can't be correct 2. The impedance of the entire circuit is measured, which is rarely correct 3. The circuit's response doesn't depend on the exact ratio of the resistors You can do an
